Structure of Higher Level Languages

Lecture 09: Dynamically-created funcs, storing funcs in lists, currying

Tiago Cogumbreiro
Module 3: Lazy evaluation
Module 3

Lazy evaluation

- Using functions to delay computation
- Lazy evaluation as a form of controlling execution
- Lazy evaluations as data-structures
- Functional patterns applied to delayed
Delayed evaluation
Recall the evaluation order

Function application

The evaluation of function application can be called\textit{eager}\text{

\begin{itemize}
\item Evaluating a function application, first evaluates each argument before evaluating the body of the function.
\end{itemize}

Condition

The evaluation of\texttt{cond} can be called\textit{lazy}, in the sense that a branch of\texttt{cond} is only evaluated when its guard yields true (and only the one branch is evaluated).
How to encode an **if-then-else**?

```
(define (factorial n)
  (cond [(= n 0) 1]
        [else (* n (factorial (- n 1)))]))
```

**Example**

```
(define (if b then-branch else-branch)
  (cond [b then-branch] [else else-branch]))

(define (factorial n)
  (if (= n 0) 1 (* n (factorial (- n 1)))))

(factorial 10)
```

What is wrong with this implementation?
How to encode an **if-then-else**?

```
(define (factorial n)
  (cond [(= n 0) 1]
        [else (* n (factorial (- n 1)))]))
```

**Example**

```
(define (if b then-branch else-branch)
  (cond [b then-branch] [else else-branch]))
```

```
(define (factorial n)
  (if (= n 0) 1 (* n (factorial (- n 1))))))
```

```
(factorial 10)
```

What is wrong with this implementation? Why `(factorial 10)` does not terminate?
Our implementation of \texttt{if} is too eager

Because our \texttt{if} is a function, applying evaluates the \texttt{then-branch} and the \texttt{else-branch} before choosing what to return.

Which, means our factorial no longer has a base case, and, therefore, it does not terminate.

\begin{verbatim}
= (factorial 0)
= (if (= 0 0) 1 (* 0 (factorial (- 0 1))))
= (if #t 1 (* 0 (factorial (- 0 1))))
= (if #t 1 (* 0 (factorial -1)))
= (if #t 1 (* 0 (if (= 0 -1) (= 0 -1) (* -1 (factorial (- -1 1)))))
= ...
\end{verbatim}

Any idea how we can work around this limitation?
Using **lambdas** to delay computation

We can use a zero-argument lambda to hold each branch, as a *lambda* delays computation!

```scheme
(define (if b then-branch else-branch)
  (cond [b (then-branch)] [else (else-branch)]))

(define (factorial n)
  (if (= n 0) (lambda () 1) (lambda () (* n (factorial (- n 1)))))

(factorial 10)
```
Thunks: zero-argument functions

The pattern of using zero-argument functions to delay evaluation is called a **thunk**. You can use thunk as a verb which is a synonym of delaying evaluation.

- `(lambda () e)` delays expression `e`
- `(e)` evaluates thunk `e` and calls that thunk
Using **thunk**

Racket offers `(thunk e)` as a short-hand notation for `(lambda () e)`; both notations are equivalent.

```scheme
(define (if b then-branch else-branch)
  (cond [b (then-branch)] [else (else-branch)]))

(define (factorial n)
  (if (= n 0) (thunk 1) (thunk (* n (factorial (- n 1))))))

(factorial 10)
```
Functional patterns: promises
Repeated delayed computation

In functional programming, there are cases where you have an intertwined pipeline of functions where a thunk might be carried around. Since, we aim at side-effect free programming models, it is wasteful to compute a thunk multiple times, when at most one would do.

Example

\[
\text{(define (runner count thunk call-back)}
\text{ (cond [(\leq count 0) (call-back (thunk) thunk)] ; invokes thunk once, and passes it along}
\text{ [else (call-back count thunk)]})
\text{ ; does not invoke thunk once)}
\]

It might not possible to know, at the function-level, if thunk was already called, as it depends on the caller and, in this case, on call-back as well.
Promises: memoize delayed computation

- `(delay e)` delays the evaluation of an expression (yielding a thunk)
- `(force e)` caches the result of evaluating `e`, so that multiple applications of that thunk return the result.

Did you know?

- Memoization: optimization technique that caches the result of an expensive function and returns the cached result
- Haskell does not share the same evaluation model as we have in Racket. Instead, all expressions of the language are lazily evaluated.
- The idea of memoized delayed evaluation provides an elegant way to parallelize code. The concept is usually known as a `future`.
- The idea of memoized delayed evaluation (promises) is also very important in asynchronous code (networking, and GUI), eg in JavaScript, in Python
Example: delay/force

Thunks

\[
\text{(define (thunk-repeat n th)} \\
\quad \text{(cond } [\text{((\leq n 0) (void))]} \\
\quad \text{[else} \\
\quad \quad \text{(th)} \\
\quad \quad \text{(thunk-repeat (- n 1) th))}] )
\]

\[
\text{(thunk-repeat 3 (thunk (sleep 1) 3))}
\]

Promises

\[
\text{(define (promise-repeat n prom)} \\
\quad \text{(cond } [\text{((\leq n 0) (void))]} \\
\quad \text{[else} \\
\quad \quad \text{(force prom)} \\
\quad \quad \text{(promise-repeat (- n 1) prom)]})
\]

\[
\text{(promise-repeat 3 (delay (sleep 1) 3))}
\]
Promises versus thunks

Accessor

- Promises: must call function `force`
- Thunks: call the object itself

Evaluation count

- `(force p)` evaluates the promise at most once; subsequent calls are cached
- `(thnk)` calling a thunk evaluates its contents each and every time
Implementing promises
Implementing promises: state

Promises are usually implemented with mutable references. Can we get away with implementing promises without using mutation?

A promise has two states:

1. when the thunk has not been run yet
2. when the thunk has been run at least once

A promise must hold:
- the thunk we want to cache
- the empty/full status

We need to separate the operations that mutate the state, from the ones that query the state.
Implementing promises: operations

Function \((\text{force\ c})\) can be though of a few smaller operations:

1. checking if the promise is empty
2. if the promise is empty, update the promise state to full and store the result of the thunk
3. if the promise is full, does nothing to the promise state, and returns the cached result

Let us separate the operations that change the state from the one that return the value.

- Function \((\text{promise-sync\ p})\) returns a new promise state. When the promise is empty, it computes the thunk and stores it in a full promise. When the promise is full, it just returns the promise given.
- Function \((\text{promise-get\ p})\) can only be called when the promise is full and returns the result of the promise.
(struct promise (empty? result))
(define (make-promise thunk) (promise #t thunk))
(define (promise-run w)
  (define th (promise-result w))
  (th))
(define (promise-get p)
  (cond [(promise-empty? p) (error "promise: call (promise-sync p) first.")] [else (promise-result p)]))
(define (promise-sync p)
  (cond [(not (promise-empty? p)) p] [else (promise #t (promise-run p))])))
Example of immutable promises

Immutable Promises

```
(define (promise-repeat n prom)
  (cond [(<= n 0) (void)]
        [else
          (promise-repeat (- n 1) (promise-sync prom))])

(promise-repeat 3 (make-promise (thunk (sleep 1) 3)))
```

Standard promises

```
(define (promise-repeat n prom)
  (cond [(<= n 0) (void)]
        [else
          (force prom)
          (promise-repeat (- n 1) prom)])

(promise-repeat 3 (delay (sleep 1) 3))
```
Streams
A stream is an infinite sequence of values.

**Did you know?** The concept of streams is also used in:

- Reactive programming (eg, a stream of GUI events for Android development)
- Stream processing for digital signal processing (eg, image/video codecs with the language StreamIt)
- Unix pipes (eg, a pipeline of Unix process producing and consuming a stream of data)
- See also Microsoft LINQ and Java 8 streams
Streams in Racket

A stream can be recursively defined as a pair holds a value and another stream:

\[
\text{stream} = (\text{cons some-value (thunk stream)})
\]

Powers of two

\[
(\text{cons 1 (thunk (cons 2 (thunk (cons 4 (thunk ...)))))}))
\]

Visually

\[
1 \quad 2 \quad 4 \quad ...
\]

Using streams

\[
\begin{align*}
&\text{(check-equal? 1 (car (powers-of-two))) ; the 1st element of the stream} \\
&\text{(check-equal? 2 (car ((cdr (powers-of-two))))) ; the 2nd element of the stream} \\
&\text{(check-equal? 4 (car ((cdr ((cdr (powers-of-two))))) ; the 3rd element of the stream}
\end{align*}
\]
Revisiting our example with helper functions

; Retrieves the current value of the stream
(define (stream-get stream) (car stream))

; Retrieves the thunk and evaluates it, returning a thunk
(define (stream-next stream) ((cdr stream)))

(check-equal? 1 (stream-get (powers-of-two)))
(check-equal? 2 (stream-get (stream-next (powers-of-two))))
(check-equal? 4 (stream-get (stream-next (stream-next (powers-of-two))))))
Count elements in stream
Programming with streams

Let us write a function that given a stream and a predicate, counts how many times a predicate holds true until it becomes false.

Spec

(check-equal? 3 (count-until (powers-of-two) (lambda (x) (< x 8))))
(check-equal? 0 (count-until (powers-of-two) (lambda (x) (<= x 0))))
(check-equal? 3 (count-until (powers-of-two) (curryr < 8))) ; Reverse Currying
(check-equal? 0 (count-until (powers-of-two) (curryr <= 0))) ; Reverse Currying
Programming with streams

Let us write a function that given a stream and a predicate, counts how many times a predicate holds true until it becomes false.

Spec

(check-equal? 3 (count-until (powers-of-two) (lambda (x) (< x 8))))
(check-equal? 0 (count-until (powers-of-two) (lambda (x) (<= x 0))))
(check-equal? 3 (count-until (powers-of-two) (curryr < 8))) ; Reverse Currying
(check-equal? 0 (count-until (powers-of-two) (curryr <= 0))) ; Reverse Currying

Solution

(define (count-until stream pred)
  (define (count-until-iter s count)
    (cond [(pred (stream-get s)) (count-until-iter (stream-next s) (+ count 1))]
      [else count])
    (count-until-iter stream 0))

  (define (count-until stream pred)
    (define (count-until-iter s count)
      (cond [(pred (stream-get s)) (count-until-iter (stream-next s) (+ count 1))]
        [else count])
      (count-until-iter stream 0))

  (define (count-until stream pred)
    (define (count-until-iter s count)
      (cond [(pred (stream-get s)) (count-until-iter (stream-next s) (+ count 1))]
        [else count])
      (count-until-iter stream 0))
Implementing powers of two
Example: powers of two

Implement the stream powers-of-two
Example: powers of two

Implement the stream powers-of-two

Solution

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
    (cons n (thunk (powers-of-two-iter (* 2 n))))
  )

(powers-of-two-iter 1)
```
The stream of constants
Example: constant

Implement a function \texttt{const} that given a value it returns a stream that always yields that value.

\begin{verbatim}
(check-equal? 20 (stream-get (const 20)))
(check-equal? 20 (stream-get (stream-next (const 20))))
(check-equal? 20 (stream-get (stream-next (stream-next (const 20)))))
\end{verbatim}
Example: constant

Implement a function \texttt{const} that given a value it returns a stream that always yields that value.

\begin{verbatim}
(check-equal? 20 (stream-get (const 20))
(check-equal? 20 (stream-get (stream-next (const 20)))
(check-equal? 20 (stream-get (stream-next (stream-next (const 20)))))
\end{verbatim}

Solution

\begin{verbatim}
(define (const v)
  (define (const-iter)
    (cons
      v
      (thunk (const-iter))))
  (const-iter))
\end{verbatim}
Common mistakes (1)

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
    (cons n (powers-of-two-iter (* 2 n))))
  (powers-of-two-iter))
```

CS450 ☾ Dynamically-created funcs, storing funcs in lists, currying ☾ Lecture 09 ☾ Tiago Cogumbreiro
Common mistakes (1)

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
    (cons n (powers-of-two-iter (* 2 n))))
  (powers-of-two-iter))
```

Forgot to guard recursion behind a thunk; endless loop.
(define (powers-of-two)
  (define (powers-of-two-iter n)
    (cons n (thunk (powers-of-two-iter (* 2 n))))))
powers-of-two-iter 1)
Common mistakes (2)

```scheme
(define (powers-of-two)
  (define (powers-of-two-iter n)
    (cons n (thunk (powers-of-two-iter (* 2 n))))))
powers-of-two-iter 1)
```

Forgot the parenthesis/forgot to call the constructor; does not return a stream.
The stream of natural numbers
A stream can be recursively defined as a pair holds a value and another stream:

\[
\text{stream} = (\text{cons some-value (thunk stream)})
\]

A stream of natural numbers:

\[
(\text{cons 0 (thunk (cons 1 (thunk (cons 2 (thunk ...))))))}\]

Visually:

\[
0 \ 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ ...
\]

Using streams:

\[
\begin{align*}
\text{(check-equal?} \ 0 \ \text{(stream-get (naturals)))} \\
\text{(check-equal?} \ 1 \ \text{(stream-get (stream-next (naturals)))}) \\
\text{(check-equal?} \ 2 \ \text{(stream-get (stream-next (stream-next (naturals))))})
\end{align*}
\]
Implement the stream of non-negative integers

0 1 2 3 4 5 6 7 ...

Spec

```racket
#lang racket
(require rackunit)

(define s0 (naturals))
(check-equal? 0 (stream-get s0))

(define s1 (stream-next s0))
(check-equal? 1 (stream-get s1))

(define s2 (stream-next s1))
(check-equal? 2 (stream-get s2))
```
Natural numbers

Implement the stream of non-negative integers

$0 \ 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ ...$

Spec

```racket
#lang racket
(require rackunit)

(define s0 (naturals))
(check-equal? 0 (stream-get s0))

(define s1 (stream-next s0))
(check-equal? 1 (stream-get s1))

(define s2 (stream-next s1))
(check-equal? 2 (stream-get s2))
```

Solution

```racket
(define (naturals)
  (define (naturals-iter n)
    (cons n
      (thunk (naturals-iter (+ n 1))))))

(naturals-iter 0)
```
