Structure of Higher Level Languages

Lecture 11: Currying, exists, update many

Tiago Cogumbreiro

Today we will learn...

- Currying (recap)
- Test if element exists (member, exists)
- Pointwise update (map)
- Tail-call optimized code

Currying

Applying a function with fewer arguments than required yields a function that expects the remaining arguments

Uncurried functions

All arguments must be provided at call-time, otherwise error.

Python example

```
def add(1, r):
    return 1 + y

add(10)
# Traceback (most recent call last):
# File "<stdin>", line 1, in <module>
# TypeError: add() missing 1 required positional argument: 'r'
```

Curried functions

If we provide one argument to a 2-parameters function, the result is a 1-parameter function that expects the second argument.

Haskell example

```
-- Define addition

add x y = x + y

-- Define adding 10 to some number

add10 = add 10

-- 10 + 30

add10 30

-- 40
```

Currying in Racket

Function curry **converts** an uncurried function into a curried function.

```
#lang racket
(define curried-add (curry +))
(define add10 (curried-add 10))
(require rackunit)
(check-equal? (+ 10 30) (add10 30))
```

HW2

- In HW2 you will need to implement the reverse, function uncurry.
- You are now ready to solve exercises 1, 4, and 5.

Currying functions

Currying is the general technique of "freezing" functions with multiple parameters. It provides a way of delaying (and caching) the passage of multiple arguments by means of new functions.

A curried function $\operatorname{curry}_{f,n,a}(x)$ is a unary function annotated with an uncurried function f arguments a and a number of expected arguments n that can be recursively defined as:

$$egin{aligned} \operatorname{curry}_{f,n+1,[a_1,\ldots,a_n]}(x) &= \operatorname{curry}_{f,n,[a_1,\ldots,a_n,x]} \ \operatorname{curry}_{f,0,[a_1,\ldots,a_n]}(x) &= f(a_1,\ldots,a_n,x) \end{aligned}$$

Exercise 6

What is the output of this program?

Program

```
(define curried-add
 (lambda (arg1)
   (lambda (arg2)
      (+ arg1 arg2))))
(define a (curried-add 10))
(define b (curried-add 20))
(a 30)
(b 40)
```

Exercise 6

What is the output of this program?

Program

Output

```
(lambda (arg2) (+ 10 arg2))
(lambda (arg2) (+ 20 arg2))
40
60
```

Functional patterns: Does it exist?

Let us implement a function member that tests whether or not a list contains a value.

Specification

```
; Unit test that tests
(require rackunit)
(check-true (member 1 (list 3 6 1)))
(check-true (member #t (list 3 #t (list))))
(check-false (member 1 (list 3 #t (list 1))))
(check-false (member #f (list)))
```

Let us implement a function member that tests whether or not a list contains a value.

Specification

```
; Unit test that tests
(require rackunit)
(check-true (member 1 (list 3 6 1)))
(check-true (member #t (list 3 #t (list))))
(check-false (member 1 (list 3 #t (list 1))))
(check-false (member #f (list)))
```

Solution

```
(define (member x 1)
  (cond
     [(empty? 1) #f]
     [(equal? (first 1) x) #t]
     [else (member x (rest 1))]))
```

Is the solution tail-recursive?

Let us implement a function member that tests whether or not a list contains a value.

Specification

```
; Unit test that tests
(require rackunit)
(check-true (member 1 (list 3 6 1)))
(check-true (member #t (list 3 #t (list))))
(check-false (member 1 (list 3 #t (list 1))))
(check-false (member #f (list)))
```

Solution

```
(define (member x 1)
  (cond
      [(empty? 1) #f]
      [(equal? (first 1) x) #t]
      [else (member x (rest 1))]))
```

Is the solution tail-recursive? **Yes!**

Overview of our solution

Recursive code mirrors the structure your data!

Think of how many constructors your data has, those will be your recursive cases.

- Case empty: the empty list constructor, same as (list)
- Case cons: add one element to the list with the (cons x 1) constructor
- Recursive call must handle "smaller" data
 - with lists: (rest 1)
 - with numbers: (+ n 1) if you approach an upper bound
 - with numbers: (- n 1) if you approach a lower bound

A general recursion pattern for handling lists

- 1. Case empty (handle-base)
- 2. Case cons (handle-step)
- 3. Recursive call handles "smaller"

```
(define (rec v)
  (cond
    [(base-case? v) (handle-base v)]
    [else (handle-step v (rec (decrement v)))]))
```

A general recursion pattern for handling lists

- 1. Case empty (handle-base)
- 2. Case cons (handle-step)
- 3. Recursive call handles "smaller"

```
(define (rec v)
  (cond
    [(base-case? v) (handle-base v)]
    [else (handle-step v (rec (decrement v)))]))
```

Example for member

```
(define (member x 1)
  (cond
    [(empty? 1) #f] ; ← handle-base: #f
    [else ; ← handle-step
        (cond [(equal? (first 1) x) #t];
        [else (member x (rest 1))])))); ← (decrement v) = (rest 1)
```

In this version, we make the base and handle-steps explicit. Previous solution coalesces nested conds into one.

Common mistake 1

Forgetting the base case

• **Symptom:** first contract violation

Example

```
(define (member x 1)
  (cond
       [(empty? 1) #f]
       [(equal? (first 1) x) #t]
       [else (member x (rest 1))]))
```

Base case missing

```
(define (member x 1)
  (cond
      [(equal? (first 1) x) #t]
      [else (member x (rest 1))]))
; first: contract violation
; expected: (and/c list? (not/c empty?))
; given: '()
; [,bt for context]
```

Common mistake 2

Forgetting to make the list smaller

• **Symptom:** program hangs (runs forever) for some inputs

Correct

```
(define (member x 1)
  (cond
      [(empty? 1) #f]
      [(equal? (first 1) x) #t]
      [else (member x (rest 1))]))
```

Incorrect

```
(define (member x 1)
  (cond
      [(empty? 1) #f]
      [(equal? (first 1) x) #t]
      [else (member x 1)]))
```

Generalizing member

Exists prefix in list?

Spec

```
(require rackunit)
(check-true (string-prefix? "Racket" "R")) ; available in standard library
(check-true (match-prefix? "R" (list "foo" "Racket")))
(check-false (match-prefix? "R" (list "foo" "bar")))
```

Exists prefix in list?

Spec

```
(require rackunit)
  (check-true (string-prefix? "Racket" "R")) ; available in standard library
  (check-true (match-prefix? "R" (list "foo" "Racket")))
  (check-false (match-prefix? "R" (list "foo" "bar")))
Solution
```

```
(define (match-prefix? prefix 1)
  (cond
  [(empty? 1) #f]
  [(string-prefix? (first 1) prefix) #t]
  [else (match-prefix? prefix (rest 1))]))
```

Can we generalize the search algorithm?

```
; Example 1
(define (member x 1)
  (cond
      [(empty? 1) #f]
      [(equal? (first 1) x) #t]
      [else (member x (rest 1))]))
```

```
; Example 2
(define (match-prefix? x 1)
  (cond
     [(empty? 1) #f]
     [(string-prefix? (first 1) x) #t]
     [else (match-prefix? x (rest 1))]))
```

Can we generalize the search algorithm?

```
; Example 1
(define (member x 1)
  (cond
      [(empty? 1) #f]
      [(equal? (first 1) x) #t]
      [else (member x (rest 1))]))
```

```
; Example 2
(define (match-prefix? x 1)
  (cond
     [(empty? 1) #f]
     [(string-prefix? (first 1) x) #t]
     [else (match-prefix? x (rest 1))]))
```

Solution

```
(define (exists predicate 1)
  (cond
    [(empty? 1) #f]
    [(predicate (first 1)) #t]
    [else (exists predicate (rest 1))]))
```

```
; Example 1
(define (member x 1)
  (exists
        (lambda (y) (equal? x y)) 1))
; Example 2
(define (match-prefix? x 1)
  (exists
        (lambda (y) (string-prefix? y x))) 1)
```

Functional pattern: Updating elements

Spec

```
(require rackunit)
; Supplied by the stdlib
(check-equal? 3 (exact-floor 3.14))
(check-equal?
  (list 1 2 3)
  (list-exact-floor (list 1.1 2.6 3.0)))
```

Convert a list from floats to integers

Spec

```
(require rackunit)
; Supplied by the stdlib
(check-equal? 3 (exact-floor 3.14))
(check-equal?
  (list 1 2 3)
   (list-exact-floor (list 1.1 2.6 3.0)))
```

Solution

Can we generalize this for any operation on lists?

```
(check-equal?
  (list-exact-floor (list 1.1 2.6 3.0)))
  (list (exact-floor 1.1) (exact-floor 2.6) (exact-floor 3.0)))
```

Function map

Generic solution

```
(define (map f 1)
  (cond [(empty? 1) 1]
       [else (cons (f (first 1)) (map f (rest 1)))]))
```

Is map function tail-recursive?

Using map

```
(define (list-exact-floor 1)
  (map exact-floor 1))
```

Function map

Generic solution

```
(define (map f 1)
  (cond [(empty? 1) 1]
       [else (cons (f (first 1)) (map f (rest 1)))]))
```

Using map

```
(define (list-exact-floor 1)
  (map exact-floor 1))
```

Is map function tail-recursive? No.

map passes the return value of the recursive call to cons. The order of applying cons is important, so we can't just apply it to an accumulator parameter (as that would reverse the order of application).

Idea: *delay adding to the right with a lambda*. First, run all recursive calls at tail-call, while creating a function that processes the result and appends the element to the left (cons). Second, run the accumulator function.

The tail-recursive optimization pattern

Tail-recursive map, using the generalized tail-recursion optimization pattern

```
(define (map f 1)
  (define (map-iter accum 1)
      (cond [(empty? 1) (accum 1)]
            [else (map-iter (lambda (x) (accum (cons (f (first 1)) x))) (rest 1))]))
  (map-iter (lambda (x) x) 1))
```

The accumulator delays the application of (cons (f (first 1))?).

- 1. The initial accumulator is (lambda (x) x), which simply returns whatever list is passed to it.
- 2. The base case triggers the computation of the accumulator, by passing it an empty list.
- 3. In the inductive case, we just augment the accumulator to take a list x, and return (cons (f (first 1)) x) to the next accumulator.

The accumulator works like a pipeline: each inductive step adds a new stage to the pipeline, and the base case runs the pipeline: (stage3 (stage2 (stage1 ((lambda (x) x) nil)))

```
(map f (list 1 2 3)) =
; First, build the pipeline accumulator
(define (accum0 x) x) (map-iter accum0 (list 1 2 3)) =
(define (accum1 x) (accum0 (cons (f 1) x))) (map-iter accum1 (list 2 3)) =
(define (accum2 x) (accum1 (cons (f 2) x))) (map-iter accum2 (list 3)) =
(define (accum3 x) (accum2 (cons (f 3) x))) (map-iter accum3 (list)) =
; Second, run the pipeline accumulator
(accum3 (list)) =
(accum2 (list (f 3))) =
(accum1 (list (f 2) (f 3))) =
(accum0 (list (f 1) (f 2) (f 3))) =
(list (f 1) (f 2) (f 3)))
```

Tail-recursive optimization pattern

To summarize, when a value has base case and an inductive case, we identified the following pattern for a tail-recursive optimization:

Unoptimized

```
(define (rec v)
  (cond
    [(base-case? v) (base v)]
    [else (step v (rec (dec v)))]))
```

Optimized
