Lecture 12: Reduction, thunks

Tiago Cogumbreiro
Today we will learn...

1. Optimizing code to be tail-recursive
2. List reduction (append, foldl)
3. Learn about delayed evaluation (thunks)

Acknowledgment: Today's lecture is partially inspired by Professor Dan Grossman's wonderful lecture in CSE341 from the University of Washington: [Video 1] [Video 2]
Making map tail-recursive

(define (map f l)
  (cond [(empty? l) l]
        [else (cons (f (first l)) (map f (rest l)))]))
Tail-recursive map run

```scheme
(map f (list 1 2 3)) =
; First, build the pipeline accumulator
(define (accum0 x) x) (map-iter accum0 (list 1 2 3)) =
(define (accum1 x) (accum0 (cons (f 1) x))) (map-iter accum1 (list 2 3)) =
(define (accum2 x) (accum1 (cons (f 2) x))) (map-iter accum2 (list 3)) =
(define (accum3 x) (accum2 (cons (f 3) x))) (map-iter accum3 (list)) =
; Second, run the pipeline accumulator
(accum3 (list)) =
(accum2 (list (f 3))) =
(accum1 (list (f 2) (f 3))) =
(accum0 (list (f 1) (f 2) (f 3))) =
(list (f 1) (f 2) (f 3))
```
Tail-recursive optimization pattern

To summarize, when a value has base case and an inductive case, we identified the following pattern for a tail-recursive optimization:

Unoptimized

```
(define (rec v)
  (cond
    [(base-case? v) (base v)]
    [else (step v (rec (dec v)))])
```

Optimized

```
(define (rec v)
  (define (rec-aux accum v)
    (cond
      [(base-case? v) (accum (base v))]
      [else
        (rec-aux
          (lambda (x) (accum (step v x)))
          (dec v))])
    )
  (rec-aux (lambda (x) x) v)
```

Tail-recursive optimization pattern

To summarize, when a value has base case and an inductive case, we identified the following pattern for a tail-recursive optimization:
Tail-recursive map, using the generalized tail-recursion optimization pattern

```
(define (map f l)
  (define (map-iter accum l)
    (cond [(empty? l) (accum l)]
      [else (map-iter (lambda (x) (accum (cons (f (first l)) x))) (rest l))])
    (map-iter (lambda (x) x) l))
```
Scanning
Remove zeros from a list

Spec

```
(require rackunit)
(check-equal? (list 1 3 4) (remove-0 (list 0 1 3 0 4)))
(check-equal? (list 1 2 3) (remove-0 (list 1 2 3)))
```
Remove zeros from a list

Spec

(require rackunit)
(check-equal? (list 1 3 4) (remove-0 (list 0 1 3 0 4)))
(check-equal? (list 1 2 3) (remove-0 (list 1 2 3)))

Solution

(define (remove-0 l)
  (cond
   [(empty? l) l]
   [(not (equal? (first l) 0)) (cons (first l) (remove-0 (rest l)))]
   [else (remove-0 (rest l))])))
Can we generalize this functional pattern?

Original

```scheme
(define (remove-0 l)
  (cond
    [(empty? l) l]
    [(not (equal? (first l) 0))
      (cons (first l) (remove-0 (rest l)))]
    [else (remove-0 (rest l))]))
```

Generalized

```scheme
(define (filter to-keep? l)
  (cond
    [(empty? l) l]
    [(to-keep? (first l))
      (cons (first l)
        (filter to-keep? (rest l)))]
    [else (filter to-keep? (rest l))])

;; Usage example
(define (remove-0 l)
  (filter
    (lambda (x) (not (equal? x 0))) l))
```

Is this function tail-recursive?
Can we generalize this functional pattern?

**Original**

```
(define (remove-0 l)
  (cond
    [(empty? l) l]
    [(not (equal? (first l) 0))
     (cons (first l) (remove-0 (rest l)))]
    [else (remove-0 (rest l))]))
```

**Generalized**

```
(define (filter to-keep? l)
  (cond
    [(empty? l) l]
    [(to-keep? (first l))
     (cons (first l)
           (filter1 to-keep? (rest l)))]
    [else (filter to-keep? (rest l))]))
```

**Usage example**

```
(define (remove-0 l)
  (filter
   (lambda (x) (not (equal? x 0))) l))
```

Is this function tail-recursive? **No.** Function **cons** is a tail-call; **filter** is not.
Tail-recursive filter

Revisiting the tail call optimization

Function \texttt{filter} has very similar shape than function \texttt{map}, so we can apply the same optimization pattern.

\begin{verbatim}
(define (filter to-keep? l)
  (define (filter-aux accum l)
    (cond
      [(empty? l) (accum l)] ; same as before
      [else
       (define hd (first l)) ; cache the head of the list
       (define tl (rest l)) ; cache the tail of the list
       (cond
         [(to-keep? hd) (filter-aux (lambda (x) (accum (cons hd x))) tl)]
         [else (filter-aux accum tl)]])
    (filter-aux (lambda (x) x) l))
\end{verbatim}
